Aurora Solar Probe — Page 1

The Aurora solar probe launched in March 2024. Its primary mission is to study solar wind patterns. The probe carries two scientific instruments: a magnetometer and a plasma spectrometer. Aurora travels on an elliptical orbit that brings it close to the Sun every five months.

Aurora Solar Probe — Page 2

The Aurora probe's magnetometer measures magnetic fields with a precision of 0.1 nanotesla. The plasma spectrometer analyzes charged particles in the solar wind. Together, the two instruments record solar wind speed, density, and temperature.

Aurora's findings will improve space weather forecasting for satellite operators. The mission is funded by the European Space Agency with a budget of 480 million euros. The mission is planned to operate for at least six years.
